The transfer of research evidence into practice has been historically slow, and requires an integration of many elements, including quality evidence, supportive physical and intellectual environments, and facilitation, as discussed at the NNEdPro Sixth International Summit on Nutrition and Health. Examples of applying clinical research into practice focused on the use of group consultations (also known as group clinics or shared medical appointments) to support behaviour change, the role of dietary micronutrients during the COVID-19 pandemic and the potential of Precision Nutrition. An emerging area from early implementation evidence includes group consultations, also known as shared medical appointments, as discussed by Dr Fallows. Group consultations have been shown to improve clinical outcomes for some patient groups (e.g., HbA1c, lipids, BMI), as well as improve self-care and health education, and patient and clinician satisfaction. These groups have been piloted throughout the UK both face-to-face and virtually, with initial findings suggesting they are feasible and acceptable to patients and clinicians. Further work is needed to assess whether these could be cost-effective when scaled-up in National Health Service UK primary care. During the COVID-19 pandemic, there has been increasing emphasis on the central role of nutrition in health, including the role of dietary micronutrients, as discussed by Dr Van Dael and Shane McAliffe. Nutrition plays an important role in immunity, yet the micronutrients, as discussed by Dr Van Dael, play a significant role in the dissemination of evidence. Once published, research is open access, disseminated widely online, and is encouraged to be used to inform practice. During the COVID-19 pandemic, any article with research findings relevant to the Coronavirus outbreak, were also shared widely with policymakers to increase global uptake. Knowledge networks, and scientific journals such as BMJ Nutrition, Prevention & Health, also play a significant role in the dissemination of evidence. Once published, research is open access, disseminated widely online, and is encouraged to be used to inform practice. During the COVID-19 pandemic, any article with research findings relevant to the Coronavirus outbreak, were also shared widely with policymakers to increase global uptake.
